ACKNOWLEDGMENT

The author is deeply indebted to Dr. Harvey R. Chaplin
for his guidance and assistance in all phases of this report.

SYMBOLS

A_j	jet area at exit, square feet
A_p	pump cross-sectional area, square feet
b	beam of bubble, feet
C_{D_e}	coefficient of external aerodynamic drag $\left(\frac{1}{5(l/b)}\right)$
C_f	turbulent skin friction coefficient $\left[0.482 \left(\log_{10} R_l \right)^{-2.618} + 0.0004 \right]$
C_L	coefficient of external aerodynamic lift
C_1	correction factor for first-order estimate of wetted area associated with "additional sidewall depth" (l_s/l)
C_2	constant which regulates pump operation $(H_p/Q^2$, for constant efficiency) , sec ² /ft ⁵
C_6	equivalent wetted depth, feet (defined by $(\frac{\text{total wetted sidewall area}}{\text{average wetted sidewall length}})$, where the numerator is the total immersed area of the sidewall when on the bubble, at zero speed and with no waves)
d_p	diameter of pump cross section, feet
D	drag, pounds
D_c	discharge coefficient $(Q/S_g V_c)$
D_w	wavemaking drag
D_e	aerodynamic drag
D_r	ram drag
$D_{s,a}$	additional sidewall drag
$D_{s,b}$	sidewall drag due to bubble
D_t	trunk drag
g	acceleration due to gravity, 32.2 ft/sec/sec
H	average wave height, feet

H_D	head loss in ducts and nozzles, feet
H_{dyn}	dynamic head at pump entrance $\left(\frac{Q^2}{2gA_p^2} \right)$, feet
H_p	pump head rise, feet
H_{spi}	static pump head at inlet, feet
H_V	vapor head, feet
h	daylight gap (for AGV), feet
h_a	additional sidewall depth, feet $(0.5 H + c_6)$
K_D	duct and nozzle loss coefficient
K_{D_D}	duct and nozzle design-speed loss coefficient
K_{D_s}	duct and nozzle static loss coefficient
K_L	total internal head loss coefficient
K_{L_D}	design internal head loss coefficient
k	velocity ratio $\left(\frac{v_j - v}{v} = \frac{\Delta v}{v} \right)$
k_{opt}	optimum velocity ratio for maximum efficiency
L	lift, pounds
l	length of bubble, feet
$\frac{l}{b}$	length/beam ratio (bubble)
l_s	wetted sidewall length, feet
n	number of wetted sides
q_a	dynamic pressure of air ($q_a \approx 0.0012 q_w$), lb/ft ²
q_w	dynamic pressure of water $(2.85 v_k^2)$, lb/ft ²
P_o	pressure of the central pressure distribution in the sequence of images, lb/ft ²
P_R	power required, lb-ft/sec

Q	volume flow rate, ft^3/sec
R_l	Reynolds number ($1.30 v_k l \times 10^5$)
S	bubble area, ft^2
S_g	air gap area (ACV), ft^2
T	thrust (= drag), pounds
V	forward velocity, ft/sec
v_D	design forward velocity, ft/sec
v_j	exit velocity, ft/sec
v_k	forward velocity, knots
v_k / \sqrt{l}	speed/length parameter
W	weight, pounds
w	specific weight (W/S), lb/ft^3
$\frac{w}{S}$	specific cushion loading, lb/ft^3
$\frac{w}{l}$	pressure/length parameter, lb/ft^3 (pressure of bubble region (w) \div length of bubble (l))
η_e	pump efficiency
η_p	propulsive efficiency
ρ_a	density of air, slugs/ ft^3
ρ_w	density of water, slugs/ ft^3
σ	cavitation index

SUMMARY

Performance predictions of Captured Air Bubble (CAB) vehicles utilizing water jet propulsion are presented. The analysis was made for various combinations of gross weight, specific loading, length-to-beam ratio, and wave height. In addition, the effect of varying the ducting loss coefficient has also been investigated.

It was found that the total drag "hump" of low length-to-beam ratios (l/b) was eliminated at higher l/b values. This effect is due to the complex behavior of the wavemaking drag component. It was further found that for a particular length-to-beam ratio (l/b), a value of specific cushion loading existed which optimized the performance (as measured by the ratio of weight to horsepower required). The lighter specific cushion loadings offered definite performance advantages at the lower length-to-beam ratios.

INTRODUCTION

Current interest in CAB vehicles has been based almost exclusively on estimates of their high-speed performance. As the theory upon which these estimates are based is updated by additional research, it is necessary from time to time to modify the original performance predictions. This report employs the most recent theory available (References 1, 2, and 3), programmed for an IBM 7090/SC-4020 computer-plotter combination. It is felt that the results presented here represent the most complete and reliable predictions available at this time.

ANALYSIS

The computer model calculates CAB performance by determining drag and power requirements at specified increments of the speed/length parameter, V_k/\sqrt{L} .

The important program inputs are: vehicle gross weight, length-to-beam ratio (l/b), specific cushion loading parameter, w/\sqrt{S} , sidewall factors C_1 and C_6 , configuration aerodynamic lift coefficient C_L , water

jet pump efficiency η_e , and duct and nozzle loss coefficient K_D . Pertinent combinations of these design parameters have been plotted and analyzed in this report. The tabulated variation is given in Table 1.

An exact formulation of the wave drag theory of Reference 2 has been incorporated into the program. However, the values on the sub-hump side are faired to a slope of 2.0 (on log-log paper), as shown in Figure 1; and secondary humps have been neglected. This fairing is essentially arbitrary, although it does agree reasonably well with the small amount of experimental data available. Experiments are presently being undertaken to ascertain the validity of this drag theory and that of Reference 1 for CAB vehicles of various length-to-beam ratios, with emphasis on the values of wavemaking drag in the sub-hump region.

The advantages of water jet propulsion in CAB applications are numerous; e.g., higher propulsive efficiencies are more readily obtainable at high speeds than is the case with conventional propellers. Since inlets and exhausts are located at or below the water line, there is relatively little potential energy loss or water weight penalty incurred (as in a hydrofoil application). Noise propagation will be less than with conventional propulsors. Debris and shallow water problems are minimized, since the entire unit may be given a low-profile configuration, particularly if multiple pump arrays are used. A variable-area intake and exit will permit large flow rates at low speeds, thus providing sufficient thrust for rapid acceleration.

Pump efficiencies of 90 percent are considered feasible for water jets. With this assumption, the propulsive efficiency (η_p) becomes dependent on the duct loss coefficient (K_D) and velocity ratio

$k = \left(\frac{V_j - V}{V} \right)$. The value of k may be optimized to give maximum η_p at a given design condition of wave height and velocity. The value of K_D is a function of the flow-through velocity and the particular ducting system utilized to channel the water to and from the pumps.

BASIC CAB PERFORMANCE EQUATIONS

The following equations are given as a concise summary of the theory developed in References 1 and 2.

(a) Wavemaking Drag (Figure 1)

$$\frac{D_w}{W} = \left[\left(\frac{w}{\lambda} \right)^2 \left(1 - 0.0012 C_L \frac{q_w}{w} \right)^2 \frac{\rho_w g D}{P_o^2 \lambda} \right] \left(\frac{\rho_w g D}{P_o^2 \lambda} \right)$$

where $\frac{\rho_w g D}{P_o^2 \lambda}$ is computed for a channel of infinite depth and width equal to ten times the bubble length by the following formula:

$$\frac{\rho_w g D}{P_o^2 \lambda} = 4 \gamma \left\{ \left(\frac{\beta}{\gamma} \sin \Omega \right)^2 + \frac{1}{4N\pi^2} + \frac{1}{\pi^2} \sum_{n=1}^N \frac{1}{n^2} \left[1 + \sqrt{1 + \left(\frac{2\pi n}{\gamma \Omega} \right)^2} \right] \right\}.$$

$$\sin^2 \left(n\pi \frac{\beta}{\gamma} \right) \cdot \sin^2 \left[\Omega \sqrt{\frac{1}{2} + \frac{1}{2} \sqrt{1 + \left(\frac{2\pi n}{\gamma \Omega} \right)^2}} \right]$$

In the above equation, the following definitions apply:

$$\beta = \frac{\text{bubble width}}{\lambda} = \frac{1}{\lambda/b}$$

$$\gamma = \frac{\text{width of channel}}{\lambda} = 10$$

$$\Omega = \frac{g\lambda}{2V^2}$$

The summation of the above equation is transmitted when

$$\frac{1}{n} \left[1 + \sqrt{1 + \left(\frac{2\pi n}{\gamma \Omega} \right)^2} \right] \leq 0.001$$

The values of $\frac{q_w g D}{P_0^2 \ell}$ versus $\frac{V}{\sqrt{\epsilon} \sqrt{s}}$ on the pre-hump side are then altered to a slope of 2 on log-log paper.

(b) Additional Sidewall Drag:

$$\frac{D_{s,a}}{W} = n \left(\frac{\ell}{b} \right) C_1 C_f \left(\frac{h_a}{\ell} \right) \frac{q_w}{w}$$

(c) Sidewall Drag Due to Bubble:

$$\frac{D_{s,b}}{W} = \left(\frac{\ell}{b} \right) C_1 C_f \left(\frac{q_w}{w} \right) \left[\frac{D_w}{W} - \frac{h}{\ell} \right]^2 \frac{1}{\frac{D_w}{W}} , \quad \frac{V_k}{\sqrt{\ell}} \geq K$$

or

$$\frac{D_{s,b}}{W} = \left(\frac{\ell}{b} \right) C_1 C_f \left(\frac{q_w}{w} \right) \left[\frac{D_w}{W} \right]_{\max} - \frac{h}{\ell}^2 \left(\frac{1}{\left(\frac{D_w}{W} \right)_{\max}} \right) , \quad \frac{V_k}{\sqrt{\ell}} < K$$

where K is the value of $V_k/\sqrt{\ell}$ taken at the wave drag "hump" $\left(\frac{D_w}{W} \right)_{\max}$ for a specified ℓ/b .

(d) Aerodynamic Drag:

$$\frac{D_e}{W} = C_{D_e} \frac{q_a}{w}$$

(e) Trunk Drag:

$$\frac{D_t}{W} = 0.00792 \left(\frac{H - 2h}{\ell} \right)^{1.2} \frac{q_w}{w} \cdot \left(\frac{b}{b + \ell} \right)$$

(f) Ram Drag:

$$\frac{D_r}{W} = 2 D_c \left(1 - C_L \frac{q_a}{w} \right)^{\frac{1}{2}} \left(\frac{q_a}{w} \right)^{\frac{1}{2}} \left(\frac{S_g}{S} \right)$$

(g) Total Drag:

$$\frac{D}{W} = \frac{D_w}{W} + \frac{D_{s,a}}{W} + \frac{D_{s,b}}{W} + \frac{D_e}{W} + \frac{D_t}{W} + \frac{D_r}{W}$$

(h) Propulsive Power-to-Weight Ratio:

$$\frac{H_p}{W} = \left(\frac{D}{W} \right) \frac{V_k}{326 \eta_p}$$

(i) Cushion Power-to-Weight Ratio:

$$\frac{H_c}{W} = 0.14 \left(\frac{D}{W} \right) \frac{V_k}{326}$$

(j) Weight-to-Horsepower Ratio:

$$\frac{W}{H_p} = \left[\frac{H_p}{W} + \frac{H_c}{W} \right]^{-1}$$

(k) Specific Power:

$$\frac{P_R}{WV} = \frac{326}{V_k (W/H_p)}$$

BASIC WATER JET EQUATIONS

As previously noted, the water jet model used in the analysis was a variable-geometry configuration for which the theory discussed in Reference 3 is appropriate. A parabolic variation of K_D with V/V_D was assumed for the duct system with the design value of K_D remaining constant at values of $V/V_D > 1.0$ (Figure 2).

The pumps were assumed to be capable of continuous operation at 90 percent efficiency η_e , while conforming to a pump head/flow rate relationship of $H_p = C_2 Q^2$. The constant C_2 is defined at a specified design speed and wave height and remains constant at all off-design conditions. The procedure for determining C_2 and other design constants is as follows:

$$\text{An optimum value of the velocity ratio, } k = \frac{V_1 - V}{V} = \frac{\Delta V}{V},$$

is determined by computing the optimum total internal loss coefficient at design conditions:

$$(a) \quad K_{L_D} = \left[1 - \frac{1}{(1 + k_{opt})^2} \right] \cdot \frac{1 - \eta_e}{\eta_e} + \frac{K_{D_D}}{\eta_e}$$

where the value $k_{opt} = \sqrt{\frac{K_L}{(1 + K_L)}}$ is determined by an iterative process. The following computations of design values are then made:

(b) Flow Rate at Design Speed:

$$Q_D = D_D / (k_{opt} V_D \rho_w)$$

(c) Exit Velocity:

$$V_{j_D} = V_D (k_{opt} + 1)$$

(d) Thrust:

$$T_D = D_D = \rho_w Q_D (V_{j_D} - V_D)$$

(e) Pump Head:

$$H_{p_D} = \frac{(1 + K_{D_D}) V_{j_D}^2 - V_D^2}{2g}$$

(f) Total Exit Area:

$$A_{j_D} = \frac{Q_D}{V_j} = Q_D \sqrt{\frac{1 + K_{D_D}}{2g H_{p_D} + V_D^2}}$$

(g) Pump Constant ($H_p = C_2 Q^2$)

$$C_2 = \frac{H_{p_D}}{Q^2} = \frac{1 + K_{D_D}}{2g A_{j_D}^2} = \frac{V_D^2}{2g Q_D^2}$$

(h) The Efficiency is given by:

$$\eta_{p_D} = \frac{2 K_D}{(1 + k_{opt})^2 (1 + K_{L_D}) - 1} = 1 - k_{opt}$$

(i) The Shaft Horsepower is given by:

$$SH = \frac{D_D V_D}{550 \eta_p}$$

and the pump diameter is determined by the empirical relation:

$$d_p = \sqrt{\frac{SH}{1000}}$$

After the design values have been determined, the program determines the off-design performance by computing for each increment of velocity the following variables:

(j) Duct Loss Coefficient (Figure 2):

$$K_D = (K_{D_s} - K_{D_D}) \left(\frac{V}{V_D} - 1 \right)^2 + K_{D_D}$$

(k) Volume Flow Rate (by iterative method).

$$D = T = \rho_w Q \left(\sqrt{\frac{2g C_2 Q^2 + V^2}{1 + K_D}} - V \right)$$

(l) Velocity Ratio:

$$k = \frac{D}{\rho_w Q V}$$

(m) Pump Head:

$$H_p = C_2 Q^2$$

(n) Exit Velocity:

$$V_j = (k + 1) V$$

(o) Nozzle Exit Area:

$$A_j = Q \sqrt{\frac{1 + K_D}{2g C_2 Q^2 + V^2}}$$

(p) Total Loss Coefficient:

$$K_L = \left[1 - \frac{1}{(1 + k)^2} \right] \frac{1 - \eta_e}{\eta_e} + \frac{K_D}{\eta_e}$$

(q) Propulsive Efficiency:

$$\eta_p = \frac{2k}{(1 + k)^2 (1 + K_L) - 1}$$

(r) A suitable indication of the onset of cavitation may be the ratio of the pump inlet static head to the pump head rise:

$$\sigma = \frac{H_{spi}}{H_p} = \frac{H_{atm} - H_V - H_D + H_{dyn} - \frac{Q^2}{2g A_p^2}}{H_p}$$

or

$$\sigma = \frac{32.51 - \frac{K_D V_j^2}{2g} + \frac{V^2}{2g} - \frac{Q^2}{2g A_p^2}}{C_2 Q^2}$$

The minimum noncavitating values of σ for specified operating conditions and duct-pump combinations have not been ascertained fully.

DISCUSSION

Table 1 shows the variation of the main design parameters evaluated by the program. Four gross weights and three length-to-beam ratios were selected as inputs. The values of l/b were 2.0, 7.0, and 3.74 (which represents the geometric mean between 2.0 and 10). The selection of design speeds and wave heights was arbitrary; however, the propulsive efficiency was insensitive to relatively large variations of these two parameters so that little benefit was realized by optimization.

Both the weight-to-horsepower ratios (W/H^P) and the specific power P_R/WV have been presented as performance figures of merit. From the standpoint of conventional power, the parameter P_R/WV affords a satisfactory prediction of the range-speed-payload capabilities of the vehicle. However, when nuclear power is considered, the principal consideration becomes the allowable weight per horsepower of the propulsion machinery, which must be a reasonable fraction of the total vehicle weight per horsepower. In the graphs of W/H^P versus V_k , W/H^P may be considered as an "equivalent" L/D ratio when plotted for a single velocity.

A study of the graphical data revealed several interesting trends in W/H^P as a function of the primary design parameters (weight, length-to-beam ratio, and specific cushion loading, w/\sqrt{S}). In general, a combination of these parameters exists that will maximize W/H^P for a given operating mode of velocity and sea state. However, due to the complexities and interactions involved in this type of analysis, it is difficult to make any simple statements on formulations with regard to optimizing performance. Rather, the procedure used here will be to illustrate graphically the optimizing trends attributed to variations of the design parameters and to indicate limiting factors in these trends.

Figure 3 is a summary plot computed from six different l/b designs of a 20,000-ton vessel operating in ten-foot waves. It should be noted that the data for this particular vessel were computed using conventional

water propellers and not water jets. A value of $w/\sqrt{S} = 1.1$ was selected, based on structural considerations. Figure 4 shows the influence of varying the specific loading w/\sqrt{S} . For a speed of 50 knots at $w/\sqrt{S} = 0.5$, the ℓ/b for best W/H is approximately 5 and, at $w/\sqrt{S} = 2.1$, the optimum ℓ/b value from a W/H standpoint is 9.0. It may be noted that the peak value of the $w/\sqrt{S} = 1.1$ curve corresponds with the value of W/H at 50 knots shown in Figure 3.

Referring again to Figure 3, it is evident that at the higher speeds the lower ℓ/b provides better performance, and the drag hump is present only at the lower ℓ/b . These phenomena are attributable directly to the nature of the wavemaking drag, as shown in Figure 1. The total drag curve (D/W) at high ℓ/b increases rapidly with velocity. As the percentage contribution of wavemaking drag is sharply reduced with increasing ℓ/b , the sidewall hydrodynamic drag begins to dominate, because of the greatly increased bubble length. The low ℓ/b advantage of super-hump operation is therefore eliminated and sub-hump operation now becomes attractive. At ℓ/b values above 7.0, the sideboard drag exceeds 80 percent of the total drag. The tradeoff beyond this point is straightforward. An increase of ℓ/b produces a decrease of the wave drag component and a corresponding increase of sidewall drag so that no net drag reduction is possible. Another drag tradeoff is evident in Figure 4. As w/\sqrt{S} increases, at any given ℓ/b , the wavemaking drag increases (D_w/W and $D_{s,b}/W$) and the sidewall hydrodynamic drag $D_{s,a}/W$ is reduced. The intersection of these drag curves represents a minimum value of total drag and an optimum of w/\sqrt{S} . This relationship is evident in Figure 4 at an ℓ/b of 9.0 where $w/\sqrt{S} = 0.5$ represents a pre-minimum value; but, at a value of 1.1, the D/W ratio is optimized. The effect of weight variation is illustrated in Figure 5.

The primary intent of this paper has been to indicate tradeoffs in performance obtainable by varying the primary design parameters. However, much additional information may be derived by studying and cross-plotting the data. In particular, the variation of the cavitation index σ with ℓ/b ,

weight, w/\sqrt{S} , wave height, and K_D is presented. Before additional refinements are added to the CAB design, the seriousness of the cavitation problem should be ascertained and modifications of K_D , pump geometry, etc. should be determined.

Multiple graphs (Figure 6 through Figure 17) have been prepared for all the data. By interpolation of these graphs, the CAB performance can be estimated. If precise information on a specific design is desired, however, a detailed computer analysis would be required.

13 ABSTRACT

Performance predictions of Captured Air Bubble (CAB) vehicles utilizing water jet propulsion are presented. The analysis was made for various combinations of gross weight, specific loading, length-to-beam ratio, and wave height. In addition, the effect of varying the ducting loss coefficient has also been investigated.

It was found that the total drag "hump" of low length-to-beam ratios (l/b) was eliminated at higher l/b values. This effect is due to the complex behavior of the wavemaking drag component. It was further found that for a particular length-to-beam ratio (l/b) a value of specific cushion loading existed which optimized the performance (as measured by the ratio of weight to horsepower required). The lighter specific cushion loadings offered definite performance advantages at the lower length-to-beam ratios.

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization (corporate author) issuing the report.	imposed by security classification, using standard statements such as:					
2a. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.	(1) "Qualified requesters may obtain copies of this report from DDC."					
2b. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.	(2) "Foreign announcement and dissemination of this report by DDC is not authorized."					
3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.	(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through _____."					
4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.	(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through _____."					
5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.	(5) "All distribution of this report is controlled. Qualified DDC users shall request through _____."					
6. REPORT DATE: Enter the date of the report as day, month, year, or month, year. If more than one date appears on the report, use date of publication.	If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.					
7a. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.	11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.					
7b. NUMBER OF REFERENCES: Enter the total number of references cited in the report.	12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring (paying for) the research and development. Include address.					
8a. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.	13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.					
8b, 8c, & 8d. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task numbers, etc.	It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as (TS), (S), (C), or (U).					
9a. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.	There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.					
9b. OTHER REPORT NUMBER(S): If the report has been assigned any other report number, either by the originator or by the sponsor, also enter this number(s).	14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.					
10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those
